

Using AI in Business Education

By: Michael B. McDonald IV, Ph.D.

Learning Outcomes

After reading this primer, you will be able to:

- | | |
|--|---|
| LO 1: Explain artificial intelligence (AI) and its role in business education | LO 4: Develop effective prompts and strategies for working with AI tools |
| LO 2: Identify appropriate uses for popular AI tools in business education | LO 5: Evaluate the risks and limitations of AI in academic and professional settings |
| LO 3: Use AI effectively for analysis and communication tasks | |

The Intern That Never Sleeps

Imagine you're in an undergraduate business class, and one of your classmates, Emma, has been struggling to keep up. She's bright but overwhelmed. One evening, while working on her assignment to analyze 5 years of financial statements for a fictional company, she discovers ChatGPT.

Emma asks, "Can you summarize trends in liquidity, profitability, and solvency from these balance sheets and income statements?" In seconds, ChatGPT produces a polished, confident narrative. Emma is amazed. She copies it into her report and moves on, grateful for the time saved.

But there's a problem. When her professor reviews the submission, several ratio trends are incorrect. ChatGPT had performed rough, text-based calculations without access to the actual numbers. Worse, it confidently stated the company had "reduced its debt-to-equity ratio," when in fact, the ratio had increased.

The issue isn't that Emma used AI—it's that she trusted it completely, treating it as a flawless analyst rather than what it really is: a capable but unreliable intern.

This primer is designed to help students like you or Emma—and their instructors—navigate this new landscape. AI tools such as ChatGPT, Gemini, and NotebookLM are transforming business education. They can draft papers, clean data, summarize court cases and opinions, and even generate formulas or perform calculations for financial models. But they also make arithmetic errors, invent quotes, and *never* warn you when they're wrong.

The goal here isn't to ban AI or embrace it uncritically. It's to show you how to use AI wisely—as a partner in learning—while maintaining the rigor, accuracy, and critical thinking that business demands.

Section 1: Introduction to AI

What Is Artificial Intelligence?

Artificial Intelligence (AI) refers to systems or machines that can perform tasks typically requiring human intelligence. This includes learning from experience (machine learning), understanding natural language, recognizing patterns, and making decisions.

AI is not a single technology but a collection of techniques and tools that enable computers to analyze data, draw conclusions, and improve their performance over time.

Key concepts in AI include:

- **Machine Learning (ML):** Algorithms that learn from data to make predictions or decisions without explicit programming.
- **Natural Language Processing (NLP):** The technology behind tools like ChatGPT, enabling machines to understand and respond to human language.
- **Neural Networks and Deep Learning:** Systems modeled after the human brain that excel at complex tasks like fraud detection.
- **Generative AI:** Tools that create new content—text, images, or even financial models—by using patterns in massive datasets.

AI is a collection of technologies that helps machines *mimic* human cognitive functions. In business education, it serves as a companion to amplify analytical skills, not as a replacement for critical thinking.

What Is an LLM and How Does It Work?

An LLM (Large Language Model) is a type of AI designed to predict and generate text. Models like ChatGPT, Gemini, and Claude are trained on billions of words from books, websites, and other texts.

At a high level, here's how they work:

- **Pattern Recognition, Not Understanding:** LLMs don't "know" facts like humans do. Instead, they recognize patterns in language and predict the next most likely word in a sequence.
- **Training Process:** During training, the model adjusts billions of internal "weights" (parameters) so it can mimic grammar, tone, and reasoning from its dataset.
- **Token by Token Generation:** When you ask a question, the model breaks your input into chunks (called tokens) and then predicts a response, token by token, until it forms a complete answer.
- **No Built-In Knowledge of Truth:** LLMs don't inherently know if their output is correct—they rely on statistical patterns from their training data. For this reason, AI tools will never state upfront when they are wrong—because they are not "right" or "wrong"—they are simply predicting what comes next in a sequence of words rather than ascribing meaning or truth to ideas behind words.

Why This Matters in Business Education

When using AI for financial analysis, remember: the model isn't doing math or "thinking" like you are. It's predicting language. The AI does not know that $2 + 2 = 4$; it simply recognizes that in its underlying data, the characters $2 + 2 =$ are typically followed by 4. That is correct in our simple example, but in more complex work, the AI is highly likely to make errors, as its predictions will not be correct. So always verify outputs, especially numbers and citations.

AI in Business: Transforming How We Work

Business has always been data-intensive, which makes it an ideal environment for AI applications.

Today many large firms use AI for tasks like:

- **Data Analysis and Pattern Recognition:** AI tools digest enormous volumes of data to uncover trends invisible to the human eye.
- **Forecasting and Modeling:** Machine learning models predict stock prices, credit defaults, and even economic shifts (albeit with limited accuracy given the inherent uncertainties of forecasting).
- **Risk Management:** AI systems monitor real-time data, helping firms proactively manage market and credit risks.
- **Operational Efficiencies:** From AI chatbots in customer service to robotic process automation (RPA) in regulatory reporting, AI streamlines routine tasks.
- **Fraud Detection and Compliance:** AI algorithms can detect fraudulent transactions as they happen and scan regulatory texts for compliance gaps.

Essentially, AI is reshaping the business landscape by improving efficiency, accuracy, and speed across key processes. Anyone entering this field must be comfortable working alongside these technologies.

AI Myths vs. Reality	
Myth	Reality
AI will replace all business professionals.	AI augments human capabilities; it automates tasks but still requires human oversight.
AI always gives accurate, unbiased answers.	AI reflects the biases and limitations of its training data; results should be critically evaluated.
Using AI with a class is “cheating.”	Responsible AI use can enhance learning if you engage with the material thoughtfully and in-line with class rules.
Only programmers can use AI effectively.	Many AI tools, like ChatGPT and Excel plugins, require no coding and are designed for end users.

Ethical Considerations and Academic Integrity

AI brings incredible capabilities but also ethical challenges.

Transparency and Bias: AI models inherit the biases of their training data. A model predicting loan defaults might reflect historical biases against certain communities. You must learn to spot and question such biases.

Over-Reliance on AI: While AI assists analysis, it should not substitute critical thinking. Understanding business assumptions is still essential.

Academic Integrity: Institutions and instructors should set clear boundaries. Acceptable uses include brainstorming ideas or checking understanding of concepts. Unacceptable—and ill-advised—uses involve outsourcing homework or essays entirely to AI tools.

Someone who outsources their homework or project is essentially gambling with their grade—the AI tool may produce acceptable work, or it could produce something that has serious errors or inadequacies, without giving them any warning at all.

Ethical AI use in education requires understanding its limits, questioning its outputs, and using it to complement—not replace—learning.

Why You Need AI Literacy

Business school graduates face a job market where AI is part of daily workflows:

- Accountants use AI to dynamically track organization performance or audit areas of concern.
- Restaurant managers use AI to optimize staff schedules, inventory management, or budgets.
- Investment bankers deploy NLP to analyze earnings call sentiment.
- Marketing managers use AI for customer segmentation or personalization of marketing campaigns.
- Firm managers can leverage ML models for more precise risk assessments.

In the classroom, AI helps to visualize Monte Carlo simulations, test valuation models, and even learn programming with AI-assisted environments.

AI fluency is a must-have skill for future business professionals, and the classroom is the best place to build it.

Key Takeaways

- AI is a collection of technologies enabling machines to mimic human cognitive abilities.
- In business, AI improves data analysis, forecasting, and operational efficiency.
- Responsible use in education requires ethical awareness and critical thinking.
- Students with AI literacy will be more competitive in a technology-driven business field.

Knowledge Check: Questions & Answers

1. What is Artificial Intelligence in business?
Answer: AI refers to systems capable of performing data analysis, forecasting, and pattern recognition that typically require human intelligence.
2. Why is AI literacy important for business students?
Answer: The business world increasingly uses AI tools; you must understand their strengths and limits to stay competitive.
3. What is an example of ethical AI use in education?
Answer: Brainstorming ideas or using AI to visualize financial data, as long as you remain actively engaged.
4. Can AI replace critical thinking in business? Why or why not?
Answer: No. AI outputs depend on human oversight to evaluate assumptions and make informed judgments, and the AI itself has no real understanding of anything, so turning over anything more than rote decisions to it can be dangerous.
5. List one common myth about AI and the reality behind it.
Answer: Myth: AI will replace all business professionals. Reality: AI augments human work but still requires oversight and decision-making.

Section 2: Using AI Tools in Business Classes

The integration of AI tools into business education is no longer a futuristic concept—it is happening now. From intelligent assistants like ChatGPT to data analysis platforms using machine learning, these technologies offer you powerful ways to explore financial concepts, analyze data, and improve productivity.

This section provides a practical overview of popular AI tools, guidance on their use in business classes, tips for prompt engineering, and advice for maximizing benefits while minimizing risks.

Popular AI Tools for Business Education

Let's start by going through some of the popular tools in AI that may be helpful to you: ChatGPT, Claude, Gemini, and Grok (LLMs).

Large Language Models like ChatGPT are conversational AI tools that can:

- Explain complex legal rulings in plain language.
- Generate examples or summarize operational or human resource reports quickly.
- Assist in drafting reports, answering problems, or acting as a thinking partner when studying.
- For instructors, it can assist in drafting case studies, problem sets, or even class syllabi and assignments.

Example use in class: If you're struggling to understand the time value of money you could use ChatGPT to get multiple explanations and practical examples, or have ChatGPT explain how a particular problem is solved.

ChatGPT is the most popular of these LLMs, but all of them are generally effective tools. There is wide divergence in what they offer under paid and free user plans, however, so it makes sense to get familiar with several options before choosing one as your default. For some, another LLM called DeepSeek may be worth considering as well. DeepSeek is an LLM created by a Chinese company, so there are security and privacy concerns around it, and it may not be available to you given the potential for universities to block access over those concerns. Those issues aside, in terms of its core functionality it is generally an excellent tool.

Why It Matters in Business Education

When using AI for financial analysis or other management-level strategy exercises, remember that most models don't have up-to-date company filings or market data unless they are RAG-enabled. Always verify AI outputs against primary sources like 10-K reports, Bloomberg terminals, or Excel calculations.

How AI Tools Learn and Retrieve Information

AI tools like ChatGPT don't "know" things the way humans do. Instead, they work based on two key processes: training and, in some cases, retrieval-augmented generation (RAG).

- **Training:** Large language models (LLMs) like ChatGPT are trained on massive datasets—books, articles, websites, and more—to recognize patterns in text. This means they can generate answers and mimic reasoning, but they don't have access to real-time information or databases unless specifically updated.

Importantly, they can also pick up errors or biases from their training data.

- **RAG (Retrieval-Augmented Generation):** Some newer AI tools use RAG to improve accuracy. Instead of relying solely on what was seen during training, these tools first search a connected knowledge base (like a set of documents or the Internet) and then use their language model to generate answers based on the retrieved information. This makes them better at citing sources and reduces the risk of "hallucinations" (fabricating facts).

Python and AI Libraries

Python is one of the most widely used programming languages in business, especially finance, and its AI libraries make it a powerful tool for students:

- **Pandas and NumPy:** For data analysis and manipulation.
- **Scikit-learn:** For building simple machine learning models like linear regressions to estimate betas or forecast cash flows.
- **TensorFlow and PyTorch:** For advanced applications such as neural networks.

Example use in class: Use Scikit-learn to create a regression model that predicts stock returns based on historical market data.

Excel with AI Plugins

Excel remains a staple in business education, and AI plugins now extend its functionality:

- **AI-powered data cleaning:** Tools like DataRobot or Excel's own AI features can clean and organize messy datasets automatically.
- **Predictive modeling:** AI-enabled add-ins can run scenario analyses or Monte Carlo simulations.

Example use in class: Automate calculations of net present value (NPV) across multiple projects with varying discount rates.

Visualization and Analytics Platforms

Tools like Tableau, Power BI, and Google Colab support AI integrations for visualizing complex data:

- Create dashboards that update dynamically based on predictive models.
- Visualize portfolio performance and efficient frontiers.

Example use in class: Build a dashboard to visualize risk-return tradeoffs for different asset allocations using historical data.

Crafting Effective AI Prompts: Levels 1, 2, and 3

The quality of an AI tool's output depends heavily on the quality of the prompt you provide. A good prompt typically has five core elements:

1. Clear Task Definition

What do you want the AI to do? Be specific about the action: explain, list, summarize, write code, create an image, etc.

2. Context and Background

What should the AI know to do this well? Provide relevant details, data, prior information, or examples so the AI understands the situation or audience.

3. Constraints or Requirements

What are the boundaries? Specify limits such as length, tone, format, style, or any "must-have" elements (e.g., "no jargon," "use APA citations," "make it suitable for high school students").

4. Audience Awareness

Who is this for? Clarify the target audience so the AI can adjust language, depth, and style accordingly.

5. Desired Output Format

What should the final output look like? Indicate if you want a list, table, bullet points, narrative, code block, slide outline, etc.

Levels of Prompt Complexity		
Level	Description	Example
Level 1	Simple prompts with minimal context. Useful for quick tasks.	“Explain the concept of a SWOT analysis in marketing.”
Level 2	Adds context and constraints for a more tailored response.	“Summarize the pros and cons of free trade for an economics undergraduate audience in 200 words.”
Level 3	Detailed prompts that include task definition, context, constraints, audience, and desired output format.	“Write a 500-word explanation of DCF analysis for MBA students, using a conversational tone, including one real-world example and a bulleted list of advantages and disadvantages.”

AI Tools: A Quick Reference Table

The table below lists popular AI tools, what they are used for, and their availability:

Tool	Use Case	Free or Paid
ChatGPT	General-purpose AI for writing, brainstorming, and explaining concepts.	Free (basic), Paid (Pro)
Anthropic Claude	Ethical AI assistant, excels at nuanced conversations and long context.	Free (limited), Paid
Gemini (Google)	Search-integrated AI for research, data analysis, and coding help.	Free (basic), Paid
Napkin.ai	Idea organization and visualization tool for brainstorming and note-taking.	Free (limited), Paid
NotebookLM	Research assistant for summarizing documents and building knowledge bases.	Free
Gamma.app	AI for creating presentations, visual storytelling, and slide content.	Free (limited), Paid
Perplexity	Search engine with AI-powered summarization and citation support.	Free
DataRobot	Automated machine learning platform for building predictive models.	Paid
Tableau with AI	Data visualization and analysis with AI-enhanced features.	Paid (academic licenses available)

Common Pitfalls and How to Avoid Them

Over-Reliance on AI Outputs

Pitfall: Don't accept AI-generated answers as correct without verifying them.

Solution: You, the human, need to critically evaluate outputs and cross-check results with financial principles or manual calculations.

Suppose you ask ChatGPT to show an image of a regular wristwatch with a time of 3:00. Often times, it can't do that. When asked if the answer is correct, it may acknowledge that it's not. When given a second chance to produce the correct answer, it may get it wrong again. You can replicate this on your own—ask ChatGPT or another AI tool to give you a picture showing any time other than 10:10, and it will most likely give you an incorrect output. Why? Because the AI is trained on large amounts of data, and for appearance purposes, most wrist watches in stores and online shops are set to 10:10 to show the hands positioned nicely. So the AI “thinks” all wrist watches should look like that; it does not know what time is; it's just predicting what seems like a logical response based on the information it has, and since almost all wrist watches are shown at 10:10, that's what it thinks is correct.

Misinterpretation of Results

Pitfall: Misunderstanding AI predictions or statistics due to lack of context.

Solution: Emphasize interpreting AI outputs in light of financial theory and real-world constraints.

It is easy to misunderstand AI-generated predictions or statistics because the tool provides outputs without context or assumptions. For example, an AI might report a company's beta as 1.2 without explaining that it was calculated over a volatile period, making it less reliable. Without this context, you might incorrectly conclude the stock is moderately risky relative to the market and use it inappropriately in a CAPM calculation.

Academic Misconduct

Pitfall: Using AI to complete assignments without engaging in the learning process.

Solution: Institutions and instructors should set clear guidelines on acceptable AI use—and this may differ by class! For instance, brainstorming or coding assistance may be acceptable, but generating entire analyses or essays is not.

Key Takeaways

- A variety of AI tools are available, each suited to different academic and professional tasks.
- Combining AI with traditional methods ensures students develop strong critical thinking skills.
- AI prompts vary in complexity; Level 3 prompts with detailed context produce the most tailored results.
- Institutions and instructors play a key role in guiding ethical and effective AI use.

Knowledge Check: Questions & Answers

1. What are the five core elements of a good AI prompt?
Answer: Clear task definition, context and background, constraints or requirements, audience awareness, and desired output format.
2. What is the difference between a Level 1 and Level 3 prompt?
Answer: Level 1 prompts are simple and provide minimal context, while Level 3 prompts are detailed and tailored with context, constraints, audience, and format specified.
3. Which AI tool is focused on creating presentations?
Answer: Gamma.app.
4. How does retrieval-augmented generation (RAG) improve AI tools?
Answer: It allows the AI to access and incorporate up-to-date external information during a query.
5. Why do AI tools generate the wrong answers at times?
Answer: AI is not “thinking” or “understanding” in the human sense. It is simply predicting what the appropriate response to a question is based on the data it has seen. So, if that data is incomplete or misleading, or even simply complex enough, the AI will often produce the wrong response.

Section 3: AI in Business Education

As AI becomes more prevalent in business and society, its influence on business education will continue to grow rapidly. AI offers students and instructors new ways to explore business concepts, draft documents, and increase productivity. However, its limitations are just as important as its strengths.

A helpful way to think about AI is as a bright, eager intern: it can complete basic tasks and generate useful drafts, but it often makes mistakes, lacks context, and requires careful supervision.

This section examines what AI tools can and cannot do effectively in business classes. It also provides guidance for instructors seeking to incorporate AI responsibly into their teaching and helps students avoid over-reliance on AI as an infallible resource.

What AI Is Suitable For

AI performs well at tasks that involve repetition, summarization, and drafting. It can accelerate workflows and help students and instructors focus on higher-level analysis and decision making.

Completing Rote and Repetitive Tasks

AI excels at automating mundane processes that don't require deep judgment. For example:

- Cleaning and formatting messy datasets.
- Generating a basic outline for a financial report.
- Drafting email templates or preliminary summaries of company filings.

In practice: You can ask AI to create a first draft of a report, legal contract, or project summary, which you can then refine and fact-check.

Drafting Clear but Basic Writing

AI can produce grammatically correct, well-structured writing quickly. It's not Shakespeare or Hemingway, but it won't make spelling or grammar mistakes.

In practice: You can use AI to draft a first pass of a discussion post or a brief memo summarizing financial ratios.

Acting as a Brainstorming Partner

AI is helpful for generating ideas or exploring different ways to approach a problem. It can suggest alternative strategies, list potential variables for a model, or propose discussion questions.

In practice: Preparing a lecture on mergers and acquisitions might use AI to brainstorm potential examples of recent M&A activity.

Key Analogy: AI as Your Intern

Think of AI as an intern:

- **Helpful:** It saves time by handling simple, repetitive tasks and giving you a starting point.
- **Unreliable:** It frequently makes mistakes and doesn't know when it's wrong.
- **Needs Oversight:** You, the "manager," are responsible for reviewing and correcting its work.

This mindset helps you use AI effectively without falling into the trap of blind trust.

What AI Is Not Suitable For

Despite its usefulness, AI has critical weaknesses that you must understand to avoid serious errors in business class work.

AI Frequently Does Math Incorrectly

AI tools are text-based systems trained on patterns in language—not calculators or spreadsheet software. As a result, they often make arithmetic, algebraic, or logical errors even in basic computations.

Examples of math errors:

- Miscalculating the future value of an annuity when solving a time value of money problem.
- Providing inconsistent results for the same cash flow projections when prompted differently.
- Making obvious mistakes in probability or regression analysis.

Why this matters in business classes: Inaccurate calculations can lead you to believe you understand business concepts and calculations when you are actually relying on flawed outputs.

AI Fabricates Quotes and References

One of the most troubling tendencies of AI tools is their tendency to "hallucinate" content—producing plausible-sounding but entirely false quotes, citations, or document references.

Examples of hallucinations:

- Attributing quotes to Warren Buffett that he never said.
- Claiming data or findings exist in a 10-K filing or academic paper when they are not actually there.
- Providing URLs or references that, upon checking, do not exist.

Why this matters in business classes: You may mistakenly assume AI-generated references are trustworthy and include them in assignments or projects, leading to embarrassingly wrong answers.

Simple hallucinations—where an AI makes something up—have lessened as the technology has advanced, but more complex hallucinations are still very common, such as making up references when they are needed as part of a larger task.

AI Never Signals When It's Wrong

AI tools present all outputs—whether accurate or completely fabricated—with the same level of confidence.

Implications:

- You may develop false confidence in AI outputs.
- Errors may go unnoticed if results are not verified independently.

AI Can Be Sycophantic

AI tools are designed to be helpful and agreeable, which means they often prioritize aligning with the user's tone or implied expectations—even when it means reinforcing a flawed idea.

Implications:

- You may mistake AI's agreement for validation of your assumptions or arguments.
- Poor reasoning or incorrect interpretations could go unchallenged because the AI doesn't push back.

Key takeaway: You must actively challenge AI outputs and seek alternative perspectives rather than assuming agreement means correctness.

The following picture illustrates this. We start with a rather silly and mundane observation—words mean what we say they mean and people invented how to spell them—but ChatGPT turns this into some sort of brilliant deduction instead of a more normal human response like asking “Huh? What are you talking about?”

The key takeaway here is that you must assume AI outputs are provisional and require validation, particularly when they involve numbers, quotations, or document-specific claims.

What AI Can and Cannot Do

What AI Can Do	What AI Cannot Do
Draft clear, grammatically correct text in relatively small quantities	Perform reliable math calculations or complex analysis
Clean and format datasets quickly	Recognize when it has made an error
Brainstorm ideas or suggest alternative approaches	Verify facts, quotes, or references in long documents
Provide a starting point for memos, reports, legal contracts, or summaries	Replace critical thinking or professional judgment
Automate repetitive tasks like data sorting or text rewriting	Understand financial context or make nuanced trade-offs

Key Insight: Treat AI like a capable but unreliable intern—it can save you time, but you’re responsible for checking every detail. With time and experience, you will get better at doing this and learn which details likely require the most scrutiny.

Strategies to Address AI Limitations

Verification as a Habit

Cross-check AI outputs with authoritative sources, such as textbooks, academic journals, and original financial documents. For calculations, reproduce results manually or in Excel.

Encourage Healthy Skepticism

Foster a mindset where you view AI as a helpful but unreliable intern—not an infallible oracle. Critical thinking and domain knowledge remain indispensable in business.

Ethical Considerations in Education

Ethics is a critical dimension of AI use in academia. You must understand the importance of transparency, accountability, and fairness when leveraging AI tools.

Standard AI Models vs. Deep Research Models

Not all AI tools are created equal. Most popular models—like standard ChatGPT or Gemini—are designed to give quick, conversational answers. They’re great for brainstorming, summarizing concepts, or drafting emails. But when you ask them to “think deeply” about complex business topics, they often miss important nuances or make surface-level observations.

This is where **deep research models** come in. Tools like **ChatGPT 5.0 Thinking** and **DeepSeek R1** are designed to handle more complex reasoning. These models can:

- Work through multi-step problems (e.g., building a full discounted cash flow model).
- Analyze larger chunks of data (like full 10-K reports).
- Maintain focus on a single question over longer conversations without “losing the thread.”

The results are likely to still contain errors for complex assignments, but these can make good starting points for the assignment nonetheless.

Why it matters in business education: When people in business use AI for rigorous analysis, they need to know whether their tool is capable of handling multi-step reasoning or if it’s better suited for surface-level drafts. Even deep research models aren’t perfect—they still require human oversight—but they are far more effective for structured problem-solving than their standard counterparts.

Key Takeaways

- AI is best for rote tasks, drafting clear but basic writing, and brainstorming ideas.
- It struggles with math, often fabricates quotes and references, and never signals when it is wrong.
- You must treat AI as a helpful but unreliable intern whose work needs careful review and correction.
- Responsible integration of AI tools in business education is helped by instructors using a scaffold learning approach and setting clear ethical guidelines.

Knowledge Check: Questions & Answers

1. Why is it helpful to think of AI as an intern?
Answer: Because AI can assist with simple, repetitive tasks and drafting, but requires oversight since it often makes mistakes.
2. What types of tasks is AI most suited for in business education?
Answer: Rote tasks, basic writing, and brainstorming—not precise calculations or nuanced analysis.
3. Why must you verify AI outputs independently?
Answer: Because AI frequently makes math errors, fabricates content, and presents all outputs with unwarranted confidence.
4. What is the main advantage of using a “Think Deeply” or deep research AI model (like ChatGPT 5.0 Thinking or Anthropic’s Claude Research) compared to a standard model?
Answer: Deep research models are better at handling complex, multi-step reasoning tasks and analyzing larger datasets, whereas standard models are optimized for quick, conversational responses and may oversimplify detailed problems.
5. Why is critical thinking still essential when using AI in business?
Answer: Because AI cannot evaluate assumptions or apply professional judgment, both of which are crucial in business.
